

# A Pareto Optimal Solution to Set Consensus

Armando Castañeda, Technion

Joint work with:

Yannai A. Gonczarowski, Hebrew U. of Jerusalem

Yoram Moses, Technion

# Synchronous Message-Passing

- $n$  sync. processes
  - Synchronous rounds
  - At most  $t < n$  crash failures
- failures
- $f$  = actual number of failures
- failures
- *Stopping* time  $\neq$  *Decision* time

# $k$ -Set Consensus [Chaudhuri in 93]

- Generalization of the Consensus task
- Processes start with inputs from a domain  $V = \{0, \dots, k\}$ 
  - Termination: Each **correct** decides a value
  - $k$ -Agreement: **correct** processes decide on **at most  $k$**  values
  - Validity: The decision of a process is the **input of a process**

# Early Deciding Protocols

- Several k-Set Consensus protocols.

Several early deciding k-Set Consensus protocols

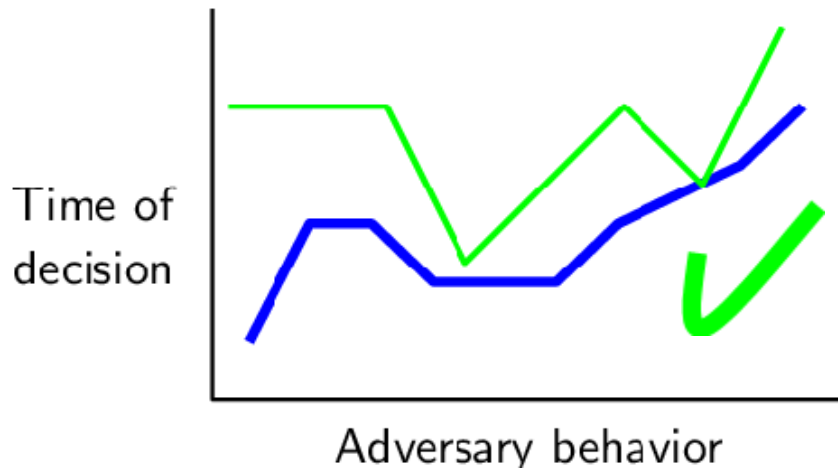

Which one is the best?

much earlier.

- **Early deciding protocols:** processes decide before the lower bound.

# Comparing Protocols (1)

- $P$  dominates  $Q$ ,  $P \leq Q$ :

- $P$  strictly dominates  $Q$ ,  $P < Q$ : if  $P \leq Q$  and a decision occurs strictly earlier in at least one case.

# Comparing Protocols (2)

- Full-information protocols

Target: THE BEST protocol for  $k$ -Set Consensus

**Impossible!!** [Moses and Tuttle 88]

for every  $A$ , for every  $i$ ,  $P(A,i) \leq Q(A,i)$

- $P$  strictly dominates  $Q$ ,  $P < Q$ :

$P \leq Q$  and there is  $A$ , there is  $i$ ,  $P(A,i) < Q(A,i)$

# No All-Case Optimal Protocol (1)

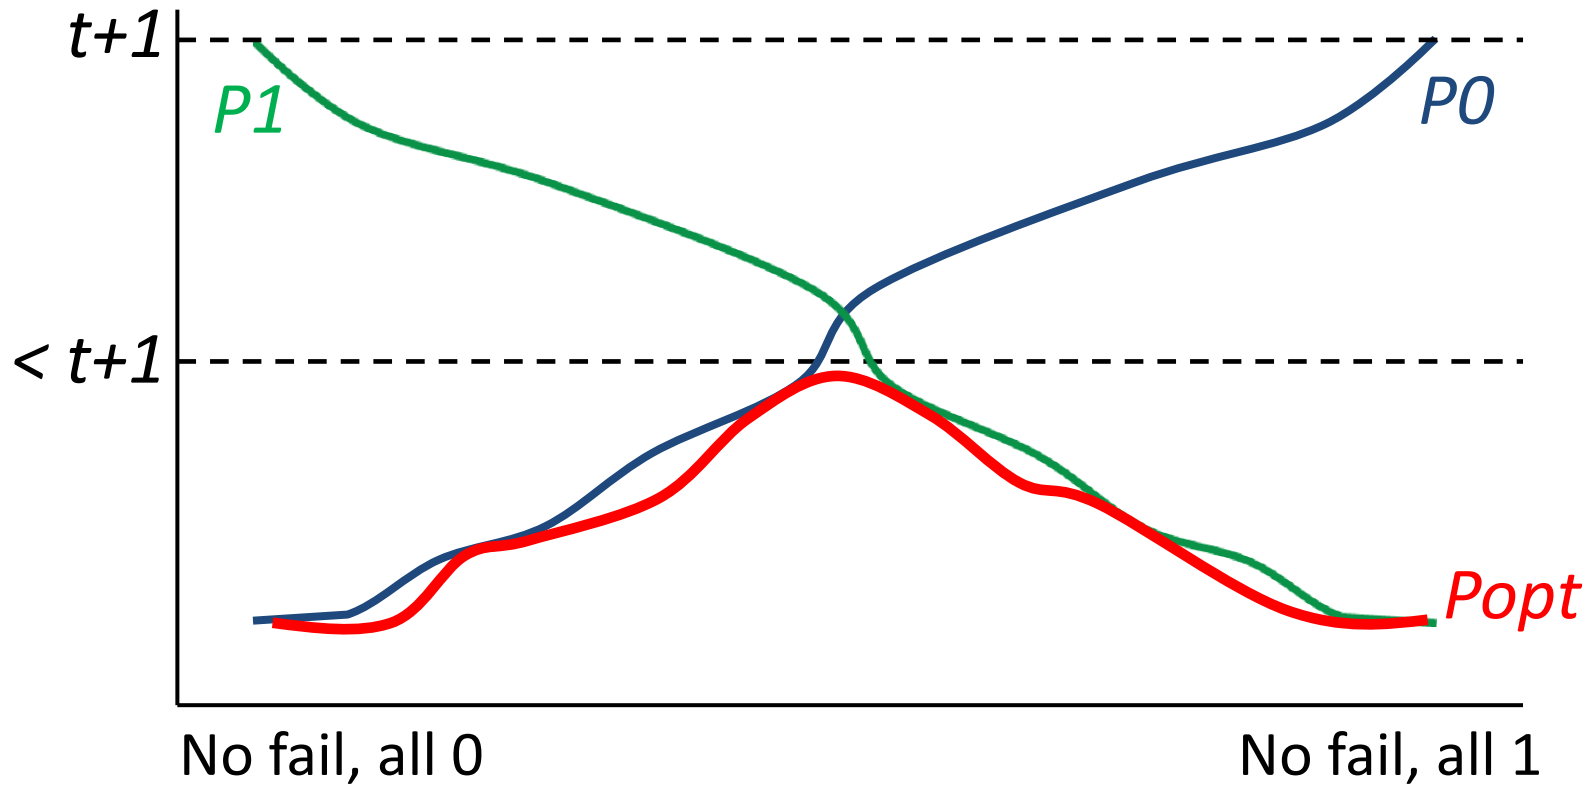

- The case of Consensus (1-Set Consensus).
- Target: Dominates **ALL** Consensus protocols.
- Protocol P0:
  - A process decides 0 **as soon it receives a 0**.
  - Otherwise **wait until round t+1** and decides 1.
- Protocol P1: similarly defined

# No All-Case Optimal Protocol (2)

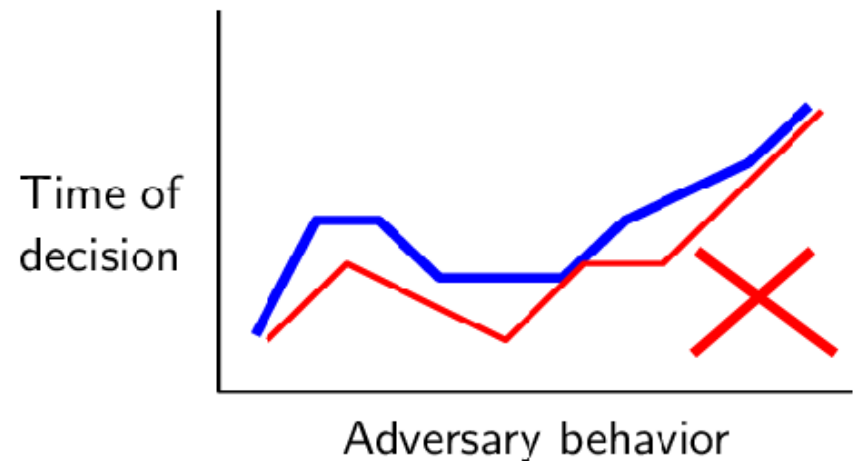

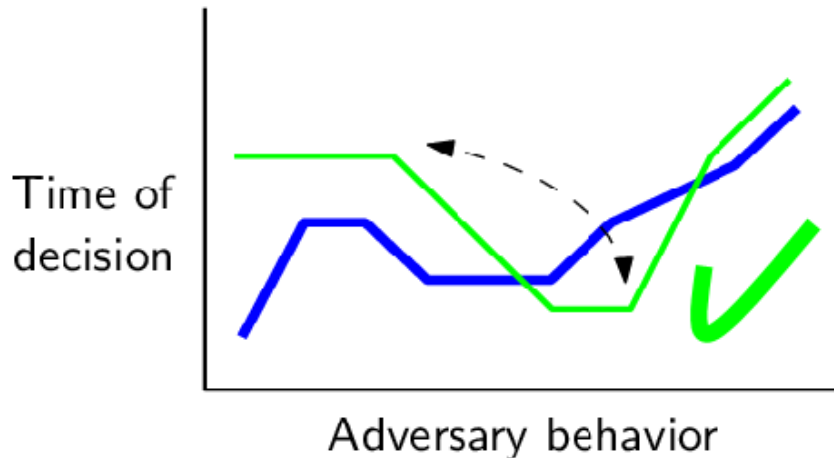

# No All-Case Optimal Protocol (2)

Contradicts the  $t+1$  Consensus lower bound!!

# Pareto Optimality (1)

- Improve at some point  $\rightarrow$  Loss at another point
- $P$  is **Pareto optimal** if for every  $Q$ , *not*  $Q \leq P$   
[Halpern et al. 2001]

# Pareto Optimality (2)

- There exist Pareto optimal protocols for Consensus [Halpern et al. 2001]
- For every consensus protocol  $P$ , there is a Pareto Optimal consensus protocol  $Q$  that dominates  $P$ .
- Cumbersome construction.

# Results (1)

- A Pareto Optimal Protocol to  $k$ -Set Consensus
- In executions with  $f$  failures:
  - Decision time:  $f/k + 1$
  - Stopping time:  $\min( f/k + 2 , t/k + 1 )$
- Pareto optimal  $\rightarrow$  Cannot strictly be improved

# Results (2)

- Our protocol **strictly dominates** all published *k*-Set Consensus Solutions [Chaudhuri et al. 2000, Gafni et al. 2011, Guerraoui and Pochon 2009, Halpern et al. 2001, Raipin Parvédy et al. 2005]
- **Optimality proof**: Knowledge-based analysis, **NO** reductions, **NO** topology

# The Case of Consensus (1)

- Inputs  $V = \{0,1\}$
- Protocol based in rules for each input value
- For process  $i$  (full-information):
  - FOR round  $r = 0, \dots, t+1$  DO
    - IF  $i$  is undecided THEN
      - IF Rule0 THEN decide 0
      - IF Rule1 THEN decide 1

# The Case of Consensus (1)

- Rule0 =  $\exists 0 = i$  receives a 0.

Processes decide 0 as soon as possible

Target: Decide 1 **as soon as it is safe** to decide 1

IF  $i$  IS undecided THEN

IF Rule0 THEN decide 0

IF Rule1 THEN decide 1

# The Rule1 (1)

- $P$  = Consensus protocol, processes decide as soon as  $\exists 0$
- **Lemma 1.** For every Consensus protocol  $Q \leq P$ , each process  $i$  decides  $0$  in  $Q$  as soon as  $\exists 0$

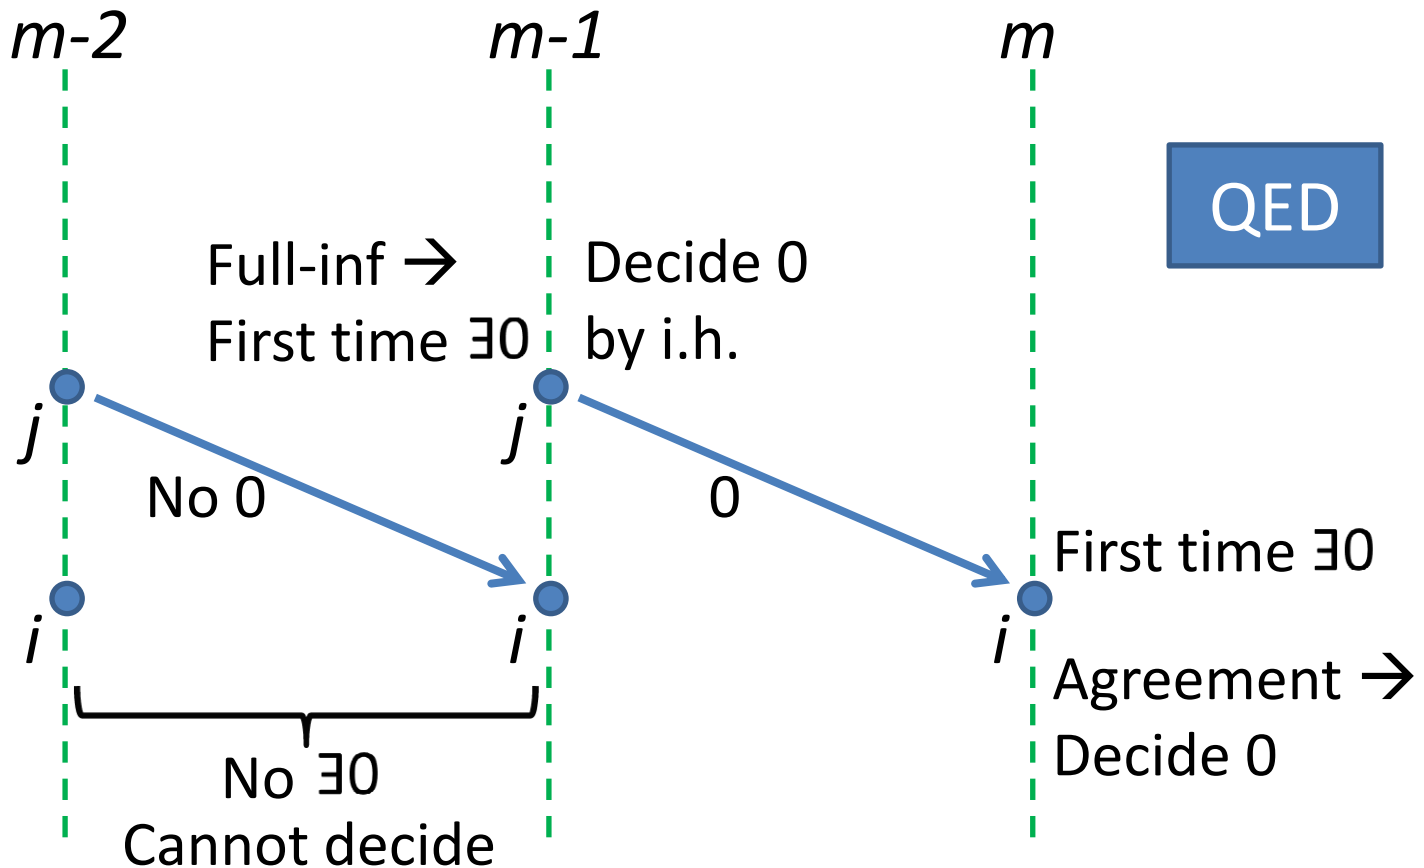

# The Rule1 (1)

- $P$  = Consensus protocol, processes decide as soon as  $\exists 0$
- **Lemma 1.** For every Consensus protocol  $Q \leq P$ , each process  $i$  decides  $0$  in  $Q$  as soon as  $\exists 0$
- **Proof:** By induction on the time  $m$ .

Base  $m = 0$ : Since  $Q \leq P$ , if  $i$  decides at time  $0$  in  $P$ , then  $i$  decides in  $Q$  at time  $0$ . Process  $i$  starts with  $0$ .

# The Rule1 (1)

Inductive step:

# The Rule1 (2)

- **Lemma 2.** For every Consensus protocol  $Q \leq P$ , if at time  $m$   $\text{NO} \exists 0$  for  $i$  and there is a **hidden path** w.r.t.  $i$ , then  $i$  **cannot** decide in  $Q$  at  $m$ .

# The Rule1 (2)

- **Lemma 2.** For every Consensus protocol  $Q \leq P$ , if at time  $m$  **NO  $\exists 0$**  for  $i$  and there is a **hidden path** w.r.t.  $i$ , then  $i$  **cannot** decide in  $Q$  at  $m$ .

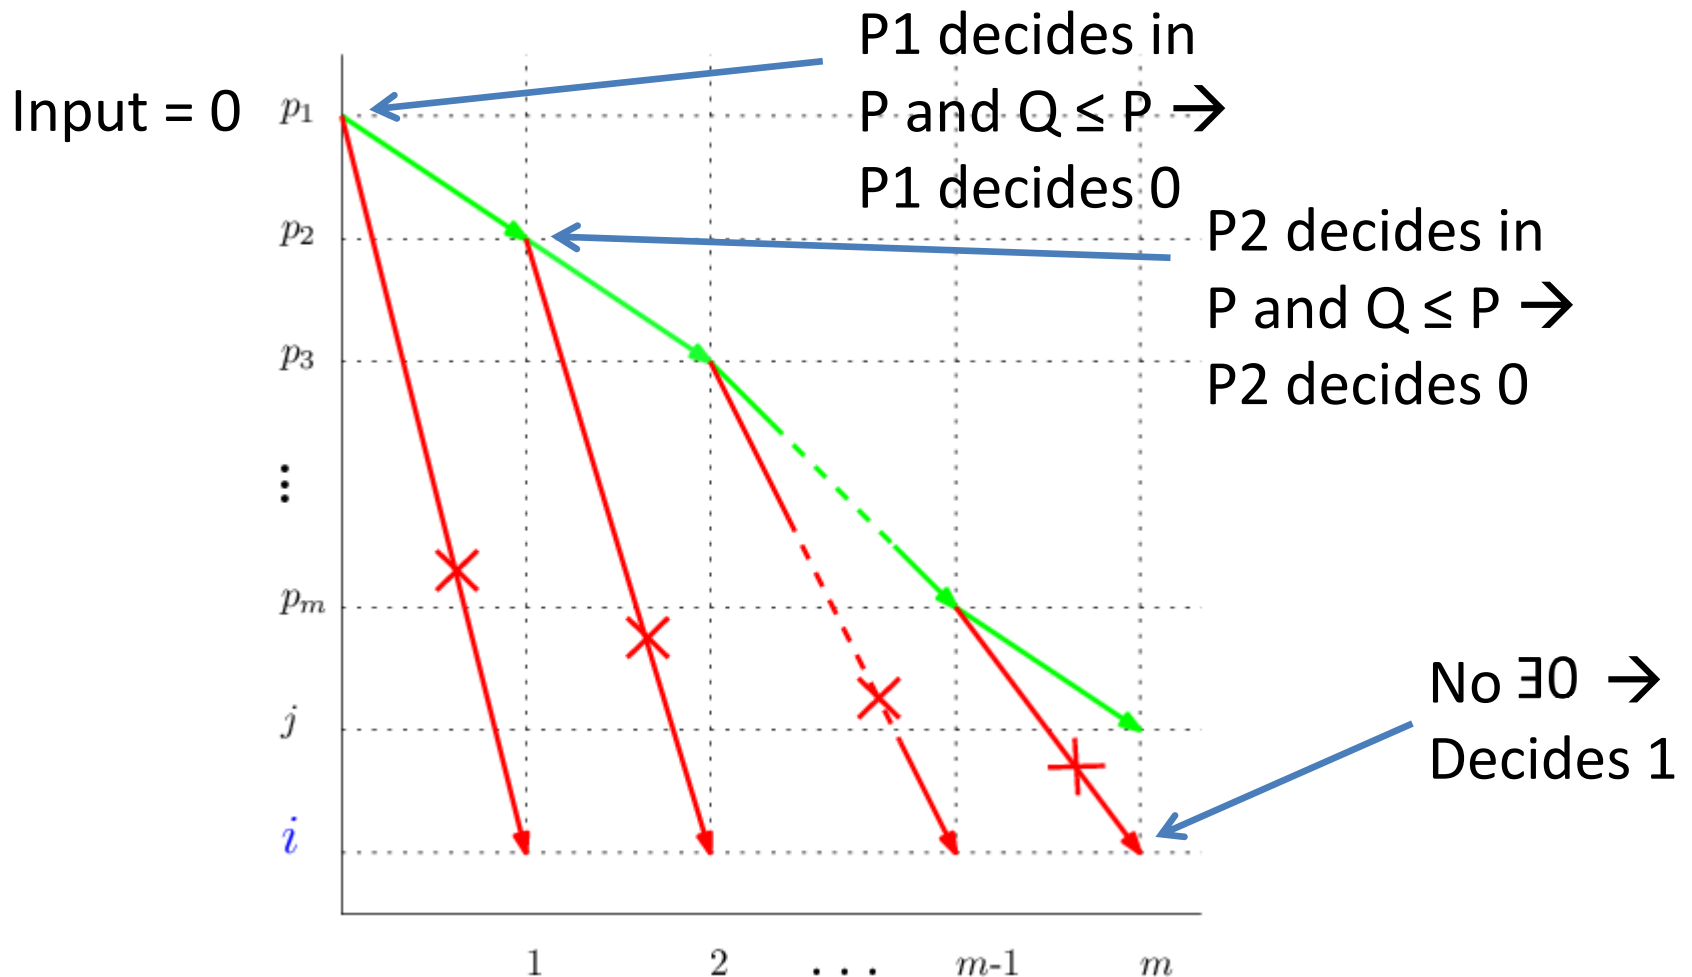

- **Hidden path** w.r.t.  $i$  at  $m$ :

*i* may not know some input values

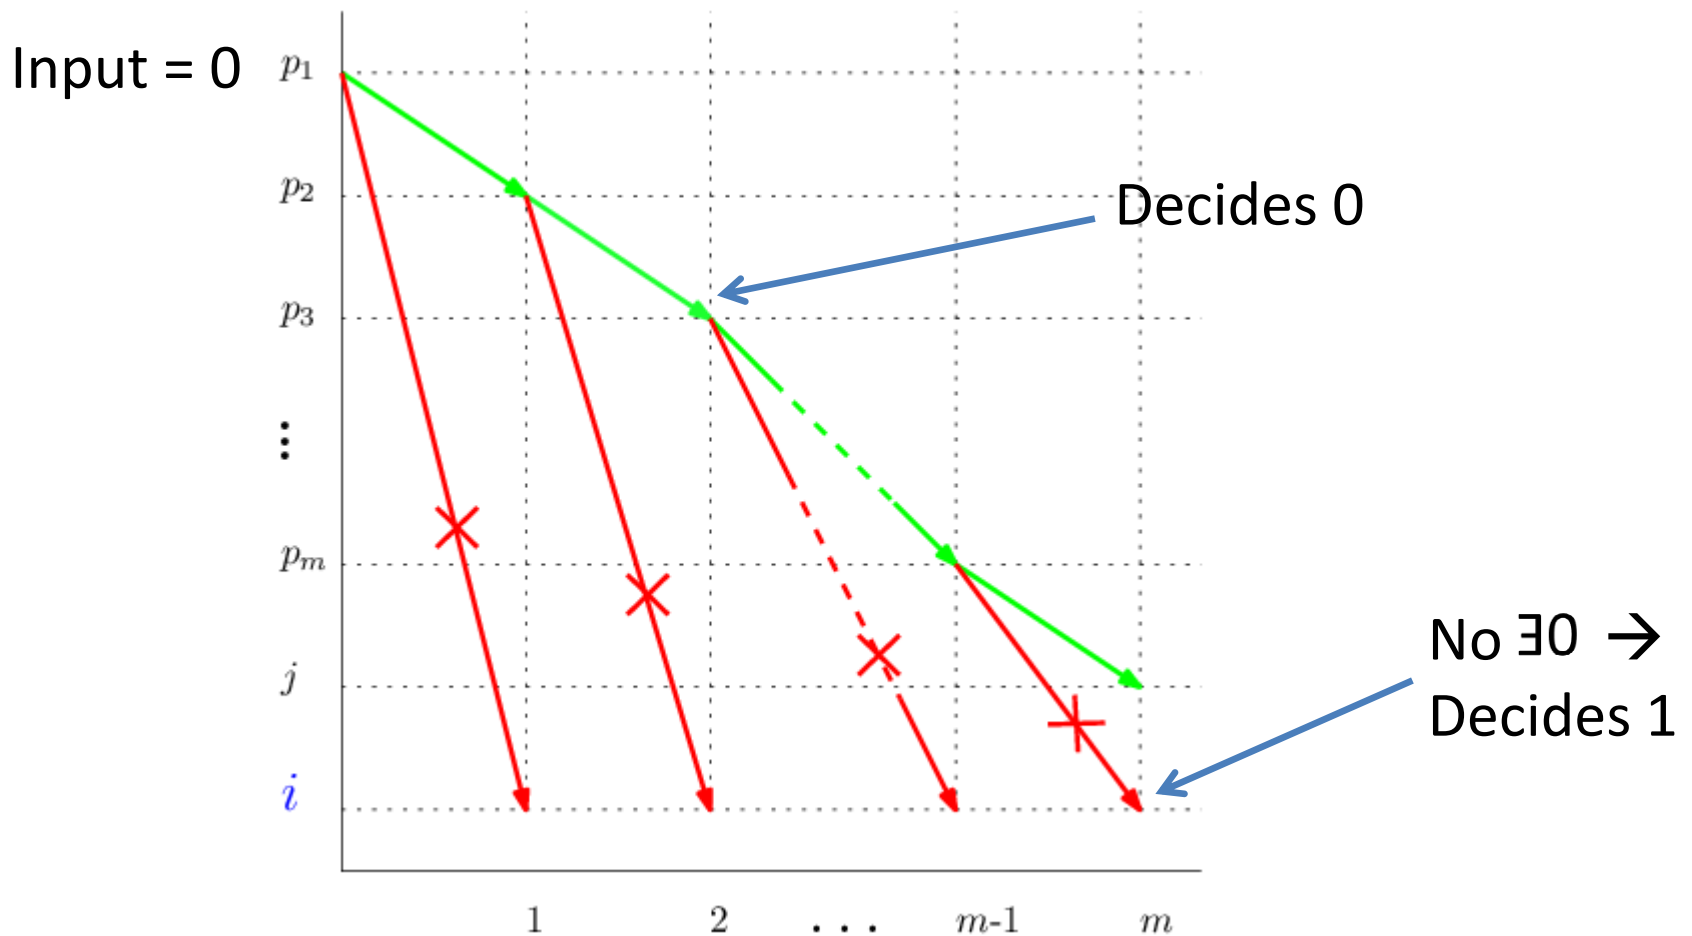

# The Rule1 (2)

- **Proof:** By contradiction,  $i$  decides at  $m$ .

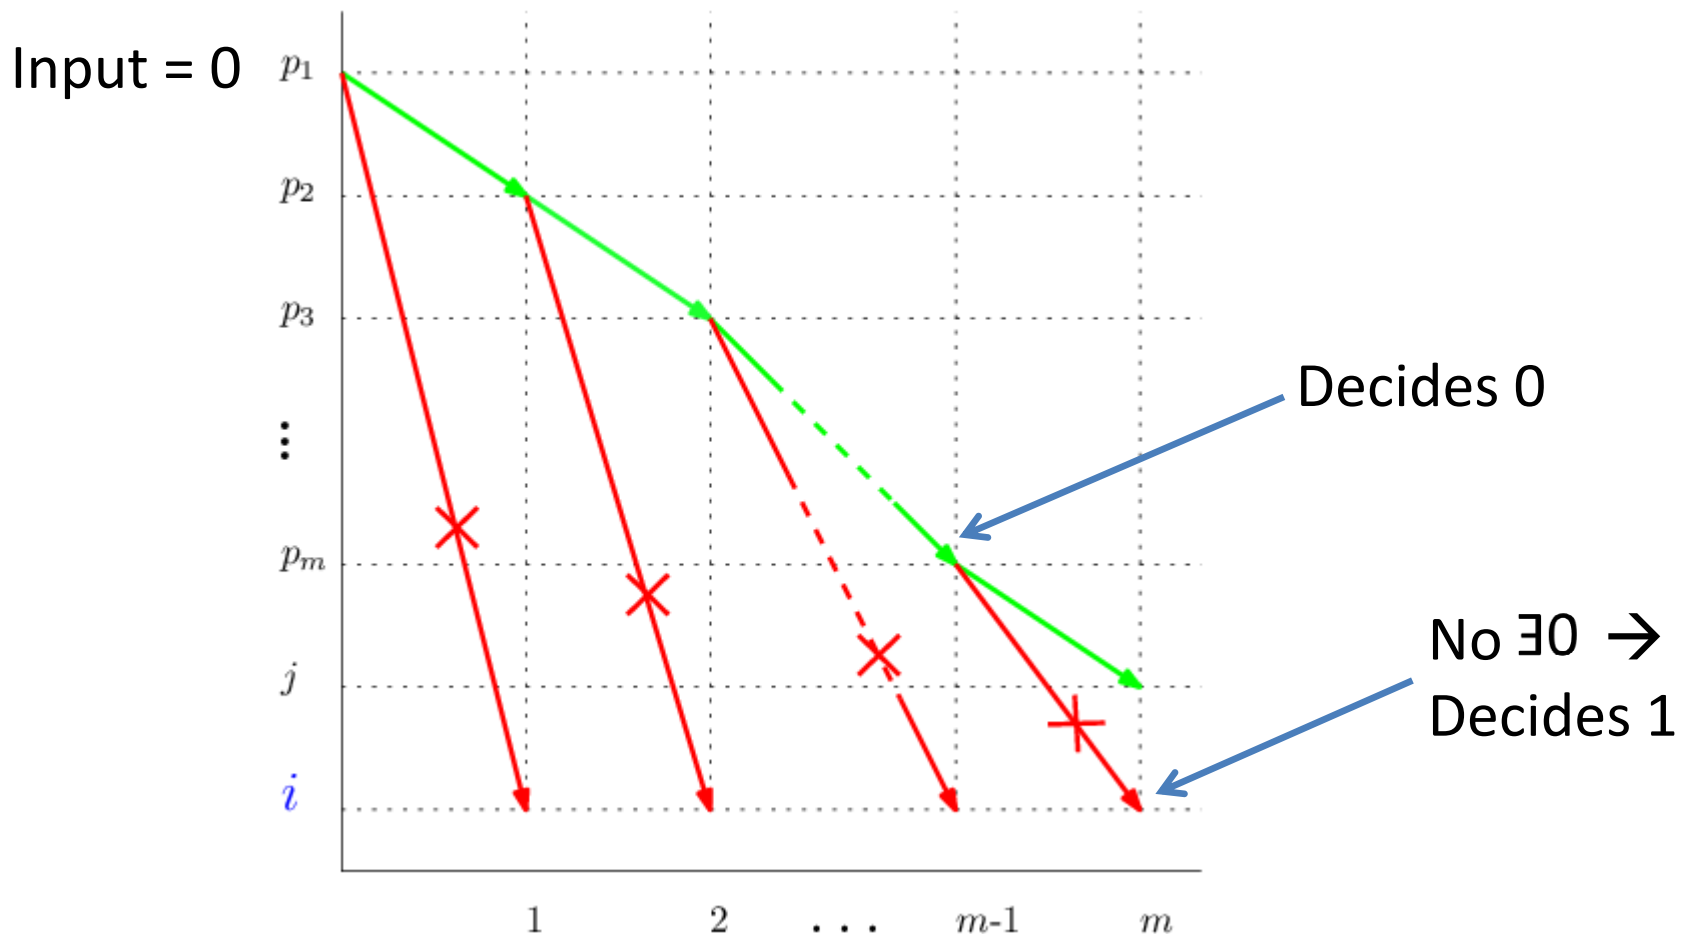

# The Rule1 (2)

- **Proof:** By contradiction,  $i$  decides at  $m$ .

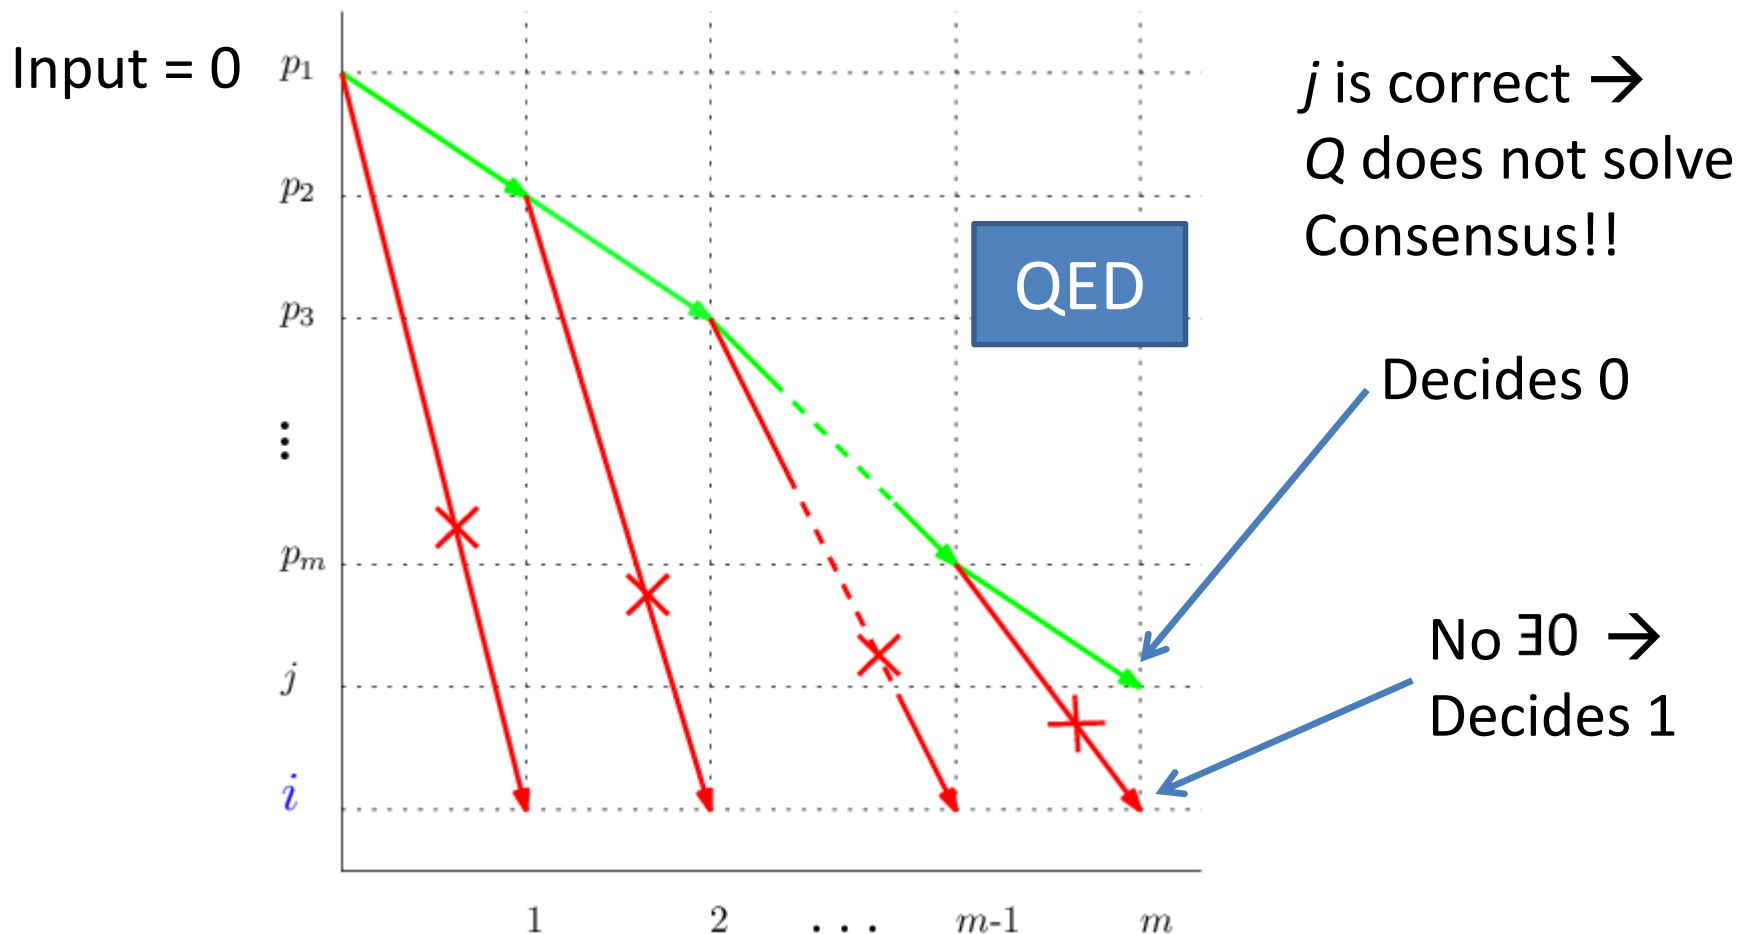

# The Rule1 (2)

- **Proof:** By contradiction,  $i$  decides at  $m$ .

# The Rule1 (2)

- **Proof:** By contradiction,  $i$  decides at  $m$ .

# The Rule1 (3)

- **Lemma 1.** For every Consensus protocol  $Q \leq P$ , each process  $i$  decides  $0$  in  $Q$  as soon as  $\exists 0$
- **Lemma 2.** For every Consensus protocol  $Q \leq P$ , if at time  $m$   $\text{NO } \exists 0$  for  $i$  and there is a hidden path w.r.t.  $i$ , then  $i$  cannot decide in  $Q$  at  $m$ .
- Lemma 1  $\rightarrow$  Rule0 is unavoidable.
- Lemma 2  $\rightarrow$  Gives Rule1, which cannot be improved.

# A Pareto Optimal Consensus Protocol

- Rule0 =  $\exists 0 = i$  receives a 0.

- 

Stopping Time: If decided in round  $r < t+1$ ,  
go one more round and then stop.  
Otherwise stop immediately.

- 

IF  $v$  IS undecided THEN

IF Rule0 THEN decide 0

IF Rule1 THEN decide 1

# The $k$ -Set Consensus Case

- Rule $v = \exists v = i$  receives a  $v$ , for  $v=0,\dots,k-1$

- Stopping Time: If decided in round  $r < t/k+1$   $k$

- Optimality Proof: Extends Lemma 1 and Lemma 2. Elementary analysis, NO reductions, NO topology.

IF Rule $v$  THEN decide  $v$

IF Rule $k$  THEN decide  $k$

# Arbitrary Large Input Domain

- $V = \{0, \dots, h\}, h \geq k.$
- RuleA =  $\exists v = i$  receives a  $v$ , for  $v=0, \dots, k-1$
- RuleB = Less than  $k$  disjoint hidden paths
- For process  $i$  (full-information):
  - FOR round  $r = 0, \dots, t/k+1$  DO
    - IF  $i$  is undecided THEN
      - IF RuleA OR RuleB THEN
        - decide min known value

# Size of Messages

- Full-information protocols **only** for analysis.
- Crash failures → **Non-exponential** size messages.
- In every round, each process only sends new information.
- Messages of **polynomial** size.

# Previous Protocols (1)

- Our protocol strictly dominates all previous  $k$ -Set Consensus solutions.
- They only look at the **current round**.
- Our protocol looks at the **past**.

# Previous Protocols (2)

# Lower Bounds for Set Consensus (1)

- Our protocol performance **contradicts** published lower bounds [Alistarh et al. 2012, Guerraoui et al. 2009, Gafni et al. 2011]
- They claim: In every protocol **NOT ALL** correct processes can **decide** in round  $f/k+1$  or earlier.
- In our protocol: **ALL** correct processes **decide** in round  $f/k+1$  or earlier.
- Source of the problem?

# Lower Bounds for Set Consensus (1)

- Our protocol performance **contradicts** published lower bounds [Alistarh et al. 2012, Guerraoui et al. 2009, Gafni et al. 2011]
- They claim: In every protocol **NOT ALL correct** processes can **decide** in round  $f/k+1$  or earlier.
- In our protocol: **ALL correct** processes **decide** in round  $f/k+1$  or earlier.
- Source of the problem?

# Lower Bounds for Set Consensus (2)

- **Non-uniform** Set Consensus:
  - **Correct processes** decide at most  $k$  values.
- **Uniform** Set Consensus:
  - **Faulty and correct processes** decide at most  $k$  values.
- Alistarh et al. 2012 and Guerraoui et al. 2009 (implicitly) assume **Uniform Set Consensus**.
- Gafni et al. 2011 (implicitly) assume **Uniform Set Consensus** in different model.

# No Topology but ...

- Guerraoui and Pochon 2009, challenge for topology techniques.
- Optimality can be proved using topology.
- Not needed because the **analysis is local**.
- Needed when the analysis is on **global decision** lower bounds.

*Thanks!!*
